

THIS LAND IS OUR LAND

35

GRADES: 7-8

SUBJECTS: Math, Social Studies

OBJECTIVE: Students will interpret NASS data to determine loss or gain of farm land and compare land in production and crop production over a 50 year period.

BACKGROUND

All living things depend on soil to live. If we had no soil we would have nothing to eat. Soil that can be used for growing food is called arable land. Every year we lose thousands of acres of arable land. Between 1990 and 2000 we lost nearly 44 million acres of arable land in the U.S. Some of the land is lost because people need places to live and build houses on it. Large portions get paved over every year for parking lots and shopping malls. Some is poisoned by industrial waste and other pollutants. Some of the land blows or washes away, and some of it just gets used up because it has been producing food year after year for many years.

Ever since George Washington conducted the first agricultural survey in our nation by gathering information about agricultural practices from his fellow farmers, conservation of farm land has been a primary concern. In 1788 he wrote, in a letter to Charles Carter, that improving "instead of exhausting our lands . . . ought to be the pursuit of every farmer. On this ground every experiment is a treasure, and the authors of them valuable members of Society."

It took many years and loss of much valuable topsoil before American farmers learned the lesson George Washington was urging on them in 1788. The most dramatic loss occurred during the early 20th Century, when wheat shortages caused by World War I caused the price of wheat to rise. Because farmers could make quite a bit of money on wheat, and because the U.S. government encouraged them to do so, farmers on the fragile southern Great Plains plowed up the natural grass cover that had pro-

 acre

tected the soil for centuries and planted winter wheat. The area suffered severe drought between 1934 and 1937. With large areas of plowed land having no grassroot system to anchor it, much of the soil simply blew away. The dust storms and sand storms buried roads and houses. Clouds of dust reached as far east as Washington, DC.

In response to the disaster, the federal government created the Soil Erosion Service and the Civilian Conservation Corps to recover the land. Workers replanted grass, planted tree wind-breaks and shelter belts and showed farmers scientific agricultural methods to help them protect the fragile ecosystem of the Southern Plains.

Farmers today are conservationists. They have to be. The land is their livelihood. And decades of conservation measures have started to pay off. The erosion rate by water on U.S. crop-lands has been reduced by 24 percent in the last 15 years. As of May, 2001, farmers had enrolled 31.4 million acres of farmland in the Conservation Reserve Program.

Although the total amount of land used for agriculture grows smaller every year, American farmers still are able to feed many more people on much less land than was possible in 1788, when George Washington was farming in Virginia. Back then one farm produced just about enough food for the family that lived on it and worked it. Today one farmer can produce enough to feed 135 people. In 1830 a farmer could produce 100 bushels of wheat on five acres of land. Today's farmer can produce the same amount on three acres, with far fewer labor hours. In 1850 the farmer could produce 100 bushels of corn on $2 \frac{1}{2}$ acres. Today's farmer can produce the same amount on one acre.

ACTIVITY

1. Use this demonstration to help students understand the importance of keeping track of land use. Tell students the apple represents the world. Use the diagram that follows to cut up the apple and explain distribution of land.
2. Divide students into five groups, and provide each group with the total land use data. Make sure students understand that the numbers are recorded per 1,000 acres. (Multiply each number by 1,000 to get the actual acreage.) Assign one decade to each group, and have the groups graph acres in agricultural use over the past 50 years.
3. Have the groups discuss their findings and write statements

about the decades they studied to share with the class. Lead a class discussion about land use. What does the data reveal about agriculture in the U.S.? Once the numbers went down did they ever go up again? Were there years when the numbers decreased at a greater rate than in previous years?

4. Have groups research the decades to which they were assigned and find factors that might have determined agricultural land use, e.g., economy, war, weather patterns, politics, etc.
5. Provide students with the charts on Student Worksheets B and C showing acres planted and production of wheat and corn. Have students graph this data. Are there years in which the production rate goes up even though the acres planted is down? Have students discuss possible reasons.

ADDITIONAL ACTIVITIES

1. Have students solve this problem: If one American farmer can feed 135 people, and there are 6 billion people in the world, how many American farmers would it take to feed all the people in the world?
2. Have students research population growth in the U.S. between 1950 and 2000 and graph those numbers with the data for land in agricultural production. Ask students to brainstorm in groups and make proposals to answer the question, "How can we continue to feed our growing population as agricultural land decreases?"
3. Have students figure the rate of agricultural land lost over the past 50 years and project rate of loss over the next 50 years. Do the same with population.
4. Have students research 1970 Nobel Prize winner Norman Borlaug and the Green Revolution to find one reason farmers are able to grow more food on less land. Students may look in the library for books and articles or use an internet search engine to find the information.
5. Have students research hydroponics and experiment with growing plants using this method.
